

Attributing risk to assets - examples from pilot projects

Dr Caroline McGahey

FRMRCII Workshop - 4th October 2011

Introduction to risk-based modelling

Pilot site examples:

- Humber Estuary
- Great Eau Catchment
- Thames Estuary

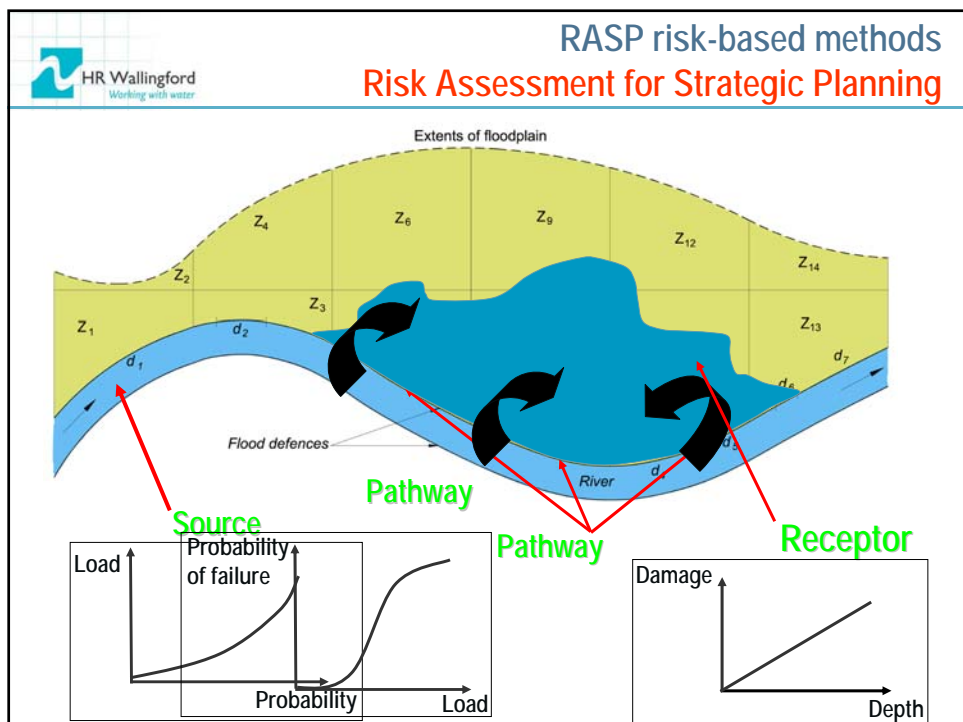

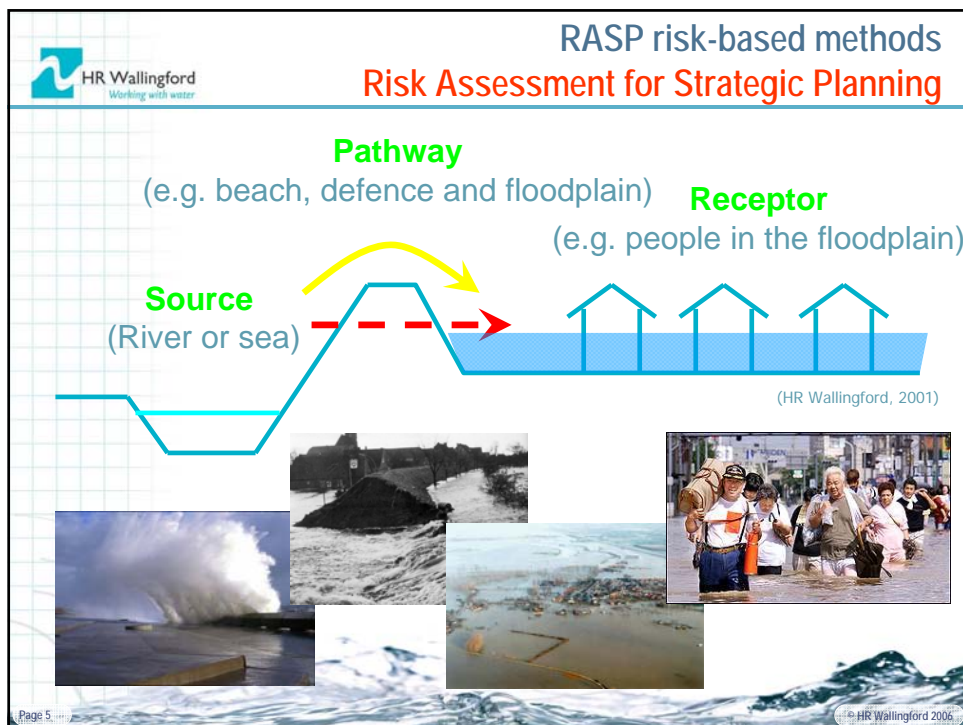

Conclusions

Why undertake risk-based modelling?

Models support rational decision making by:

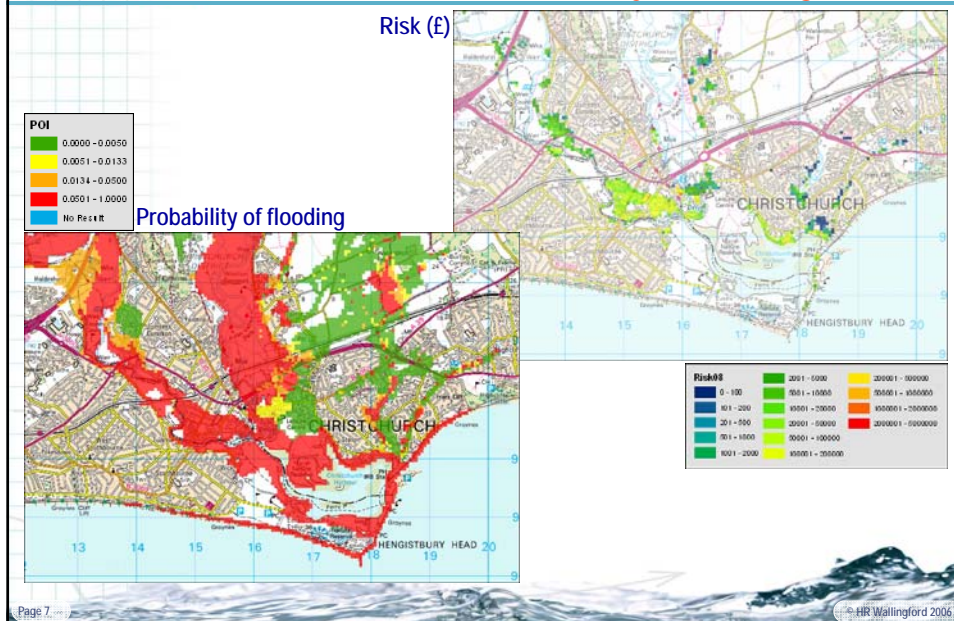

- Providing an objective understanding of system behaviour
- Providing richer information (*drives down costs*)
- Promoting focused dialogue between stakeholders

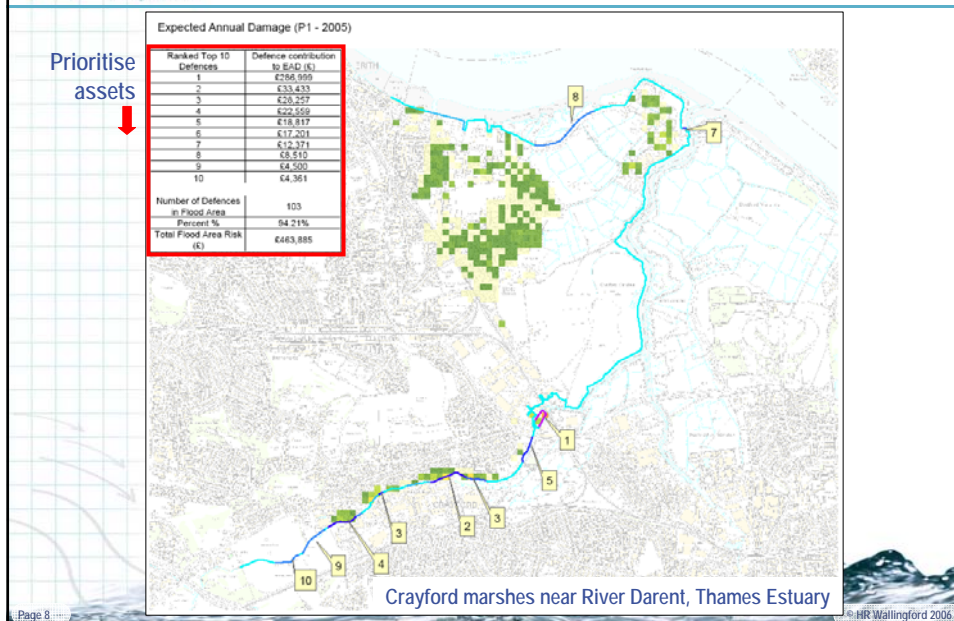

Example outputs

Probability of flooding and risk

Example outputs

 Working with water

Benefits of the RASP approach

Risk Assessment for Strategic Planning

Consistent approach

Consistent data

Consistent methodology

Providing a consistent framework

Utilising local modelling

Demonstrating the value of local modelling

A practical framework for progressively refining a risk assessment

Results - risk

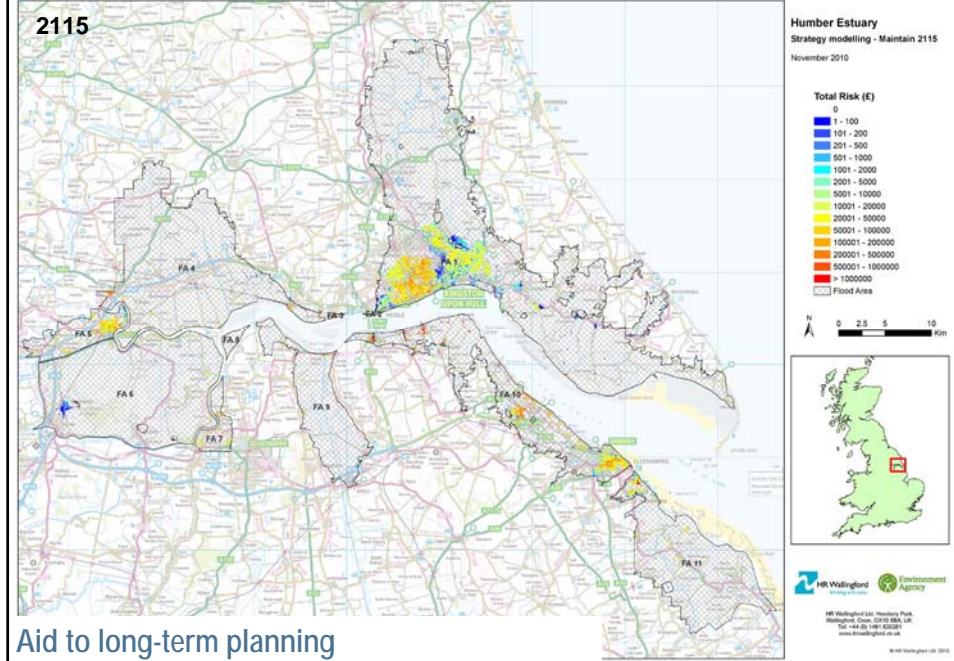

Results - risk attribution to assets

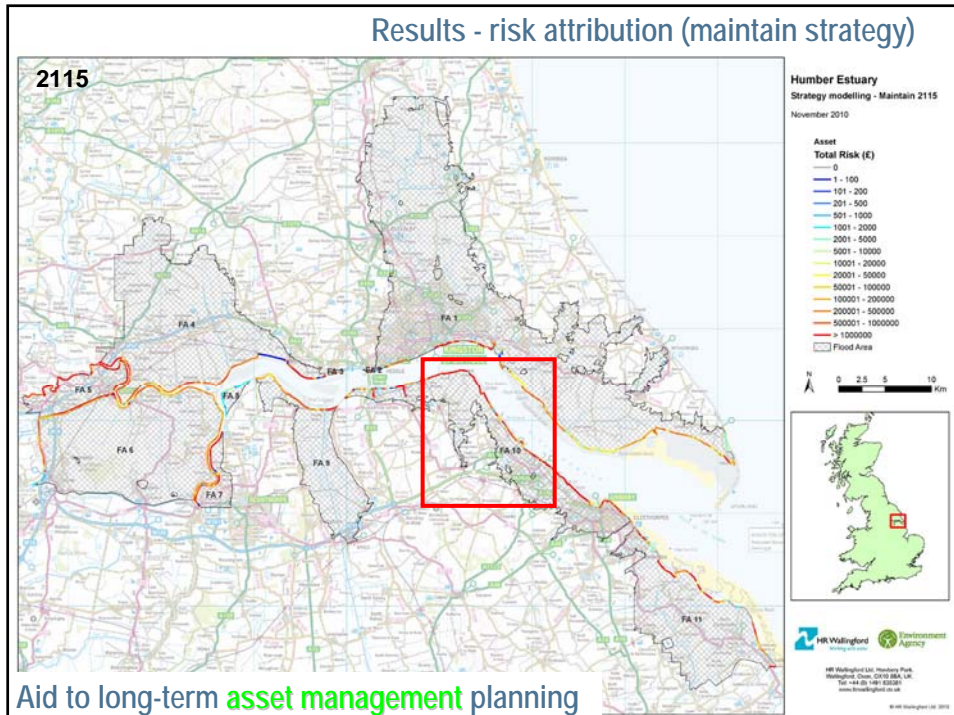

Results - risk (maintain strategy)

Results - risk attribution (maintain strategy)

Results provide insight into physical processes Risk attribution 2085

Exploring management options

Vegetation management

1) Do Nothing

2) Business as usual

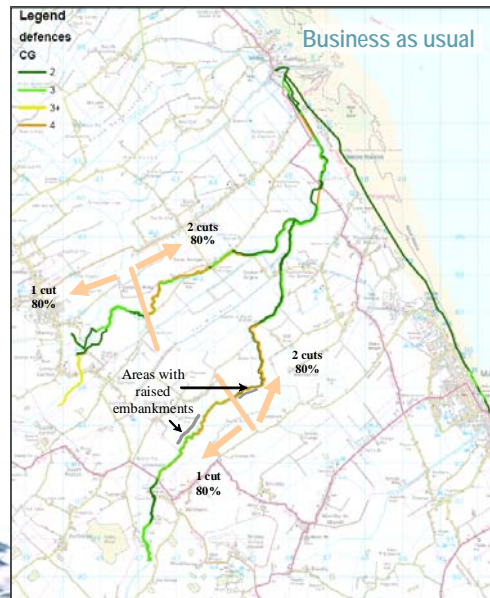

1 cutting - 15/9

2 cuttings - 15/07 and 15/10

3) Increased maintenance

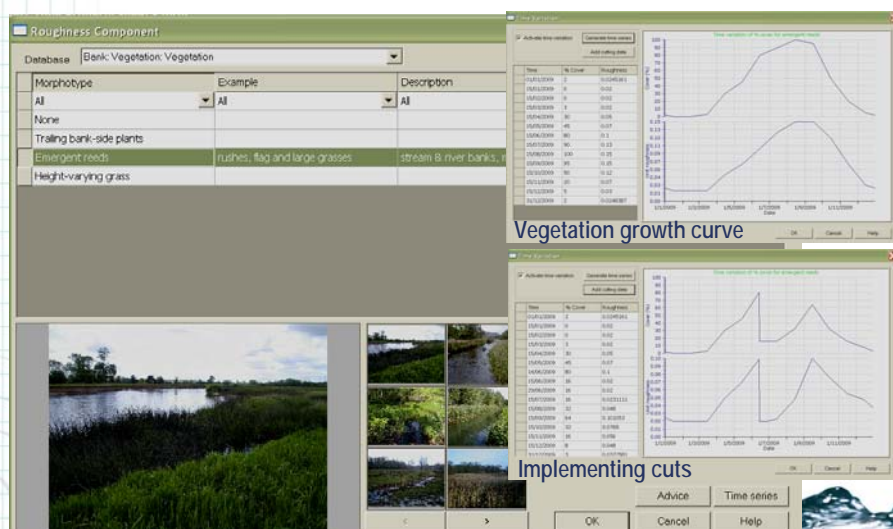

Cutting 95%

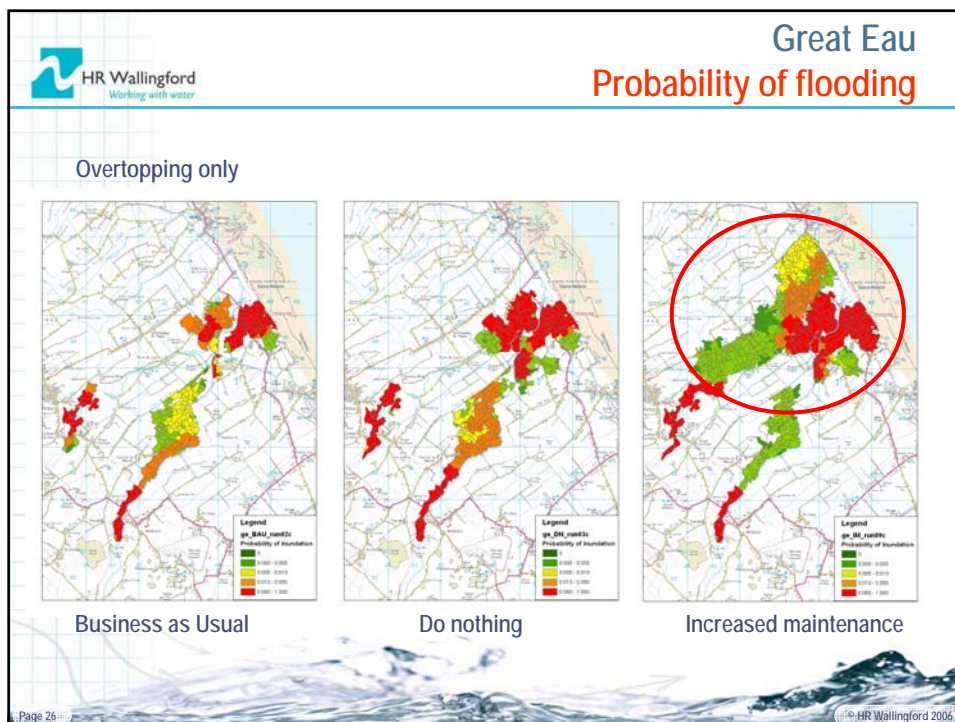

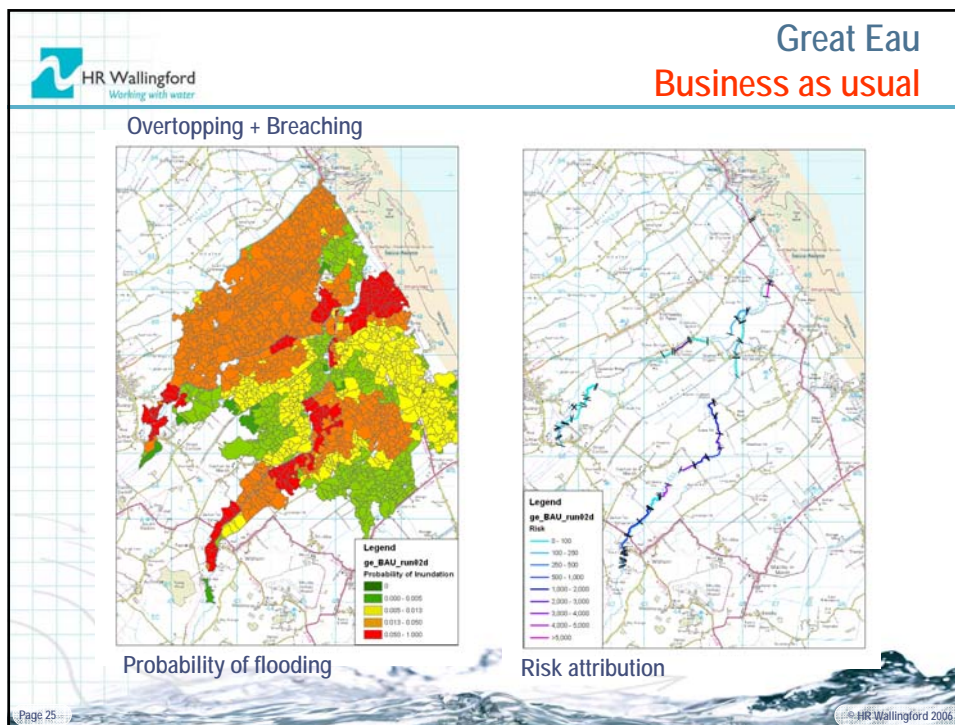

In the upper reach: 2 cuts

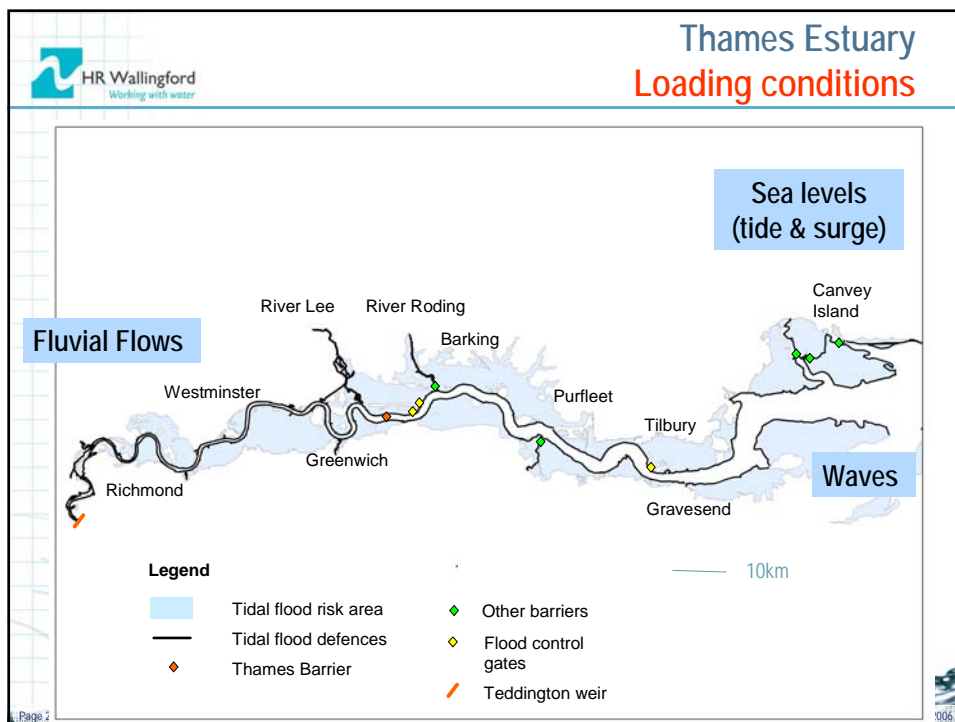

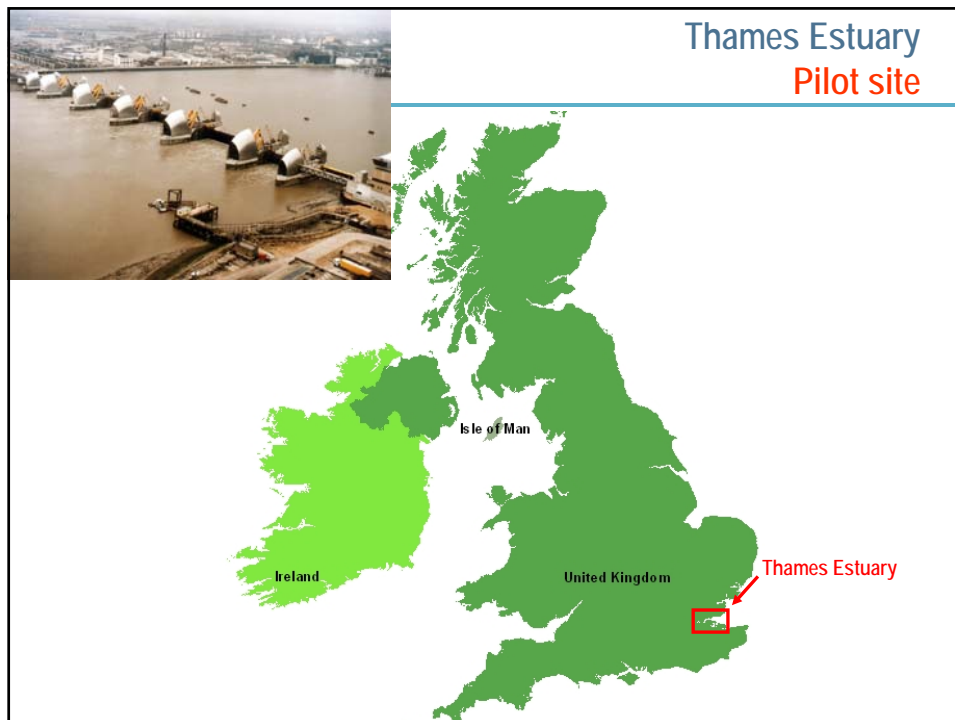

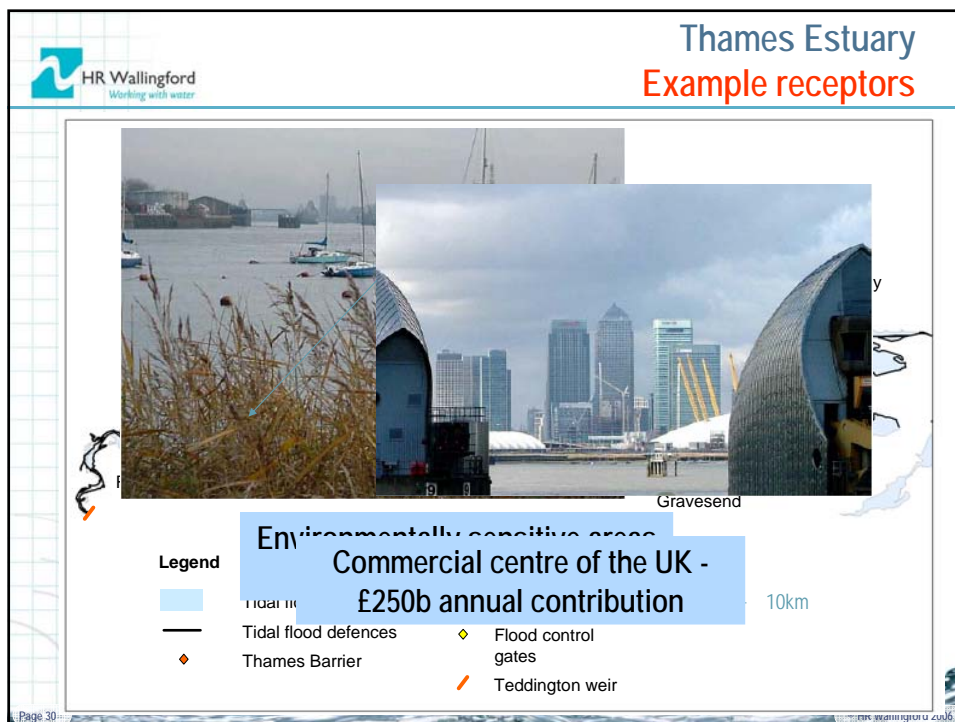

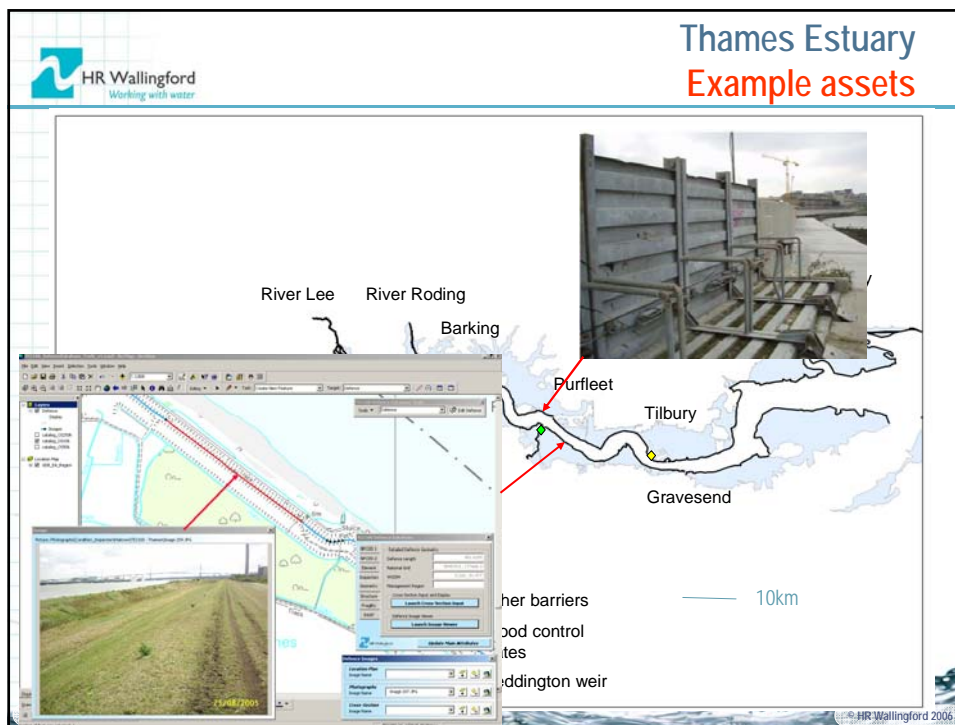

Modelling maintenance options

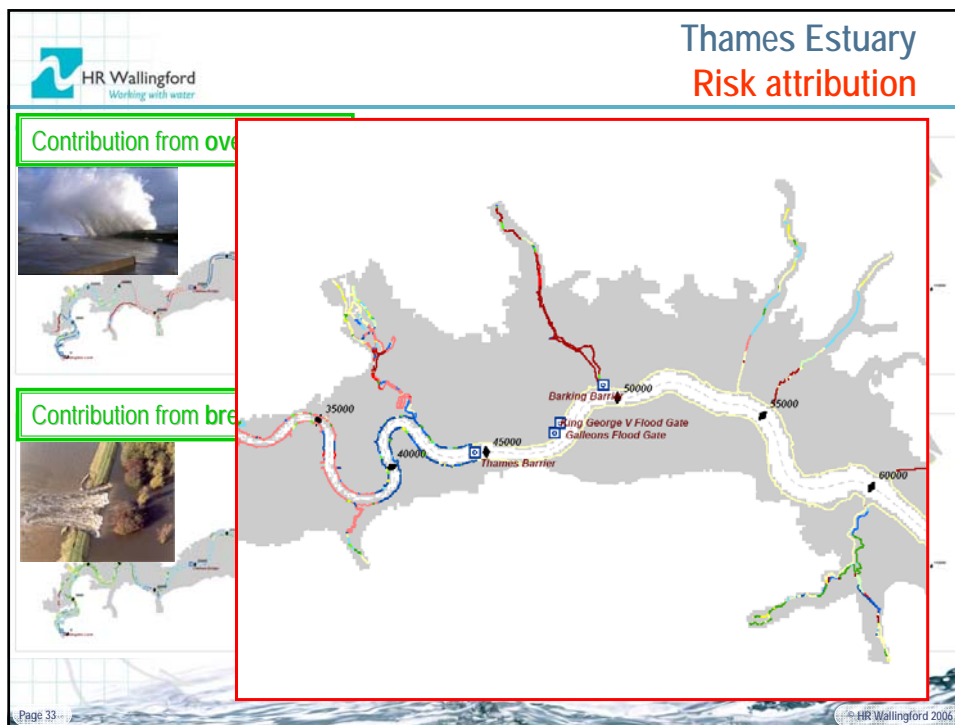

Conveyance and Afflux Estimation System (CES-AES)

HR Wallingford
Working with water

Conclusions

Flood risk system is complex

Asset managers require structured support to make sense of this

A system-based approach helps as it:

- Considers the system as a whole
- Considers asset performance
- Helps to prioritise data gathering activities
- Provides "rich" unbiased evidence to help justify asset management spend (maintenance, strengthening, raising)
- Provides a powerful tool for "what-if scenario" modelling (e.g. asset deterioration, long-term options)
